Research topic week2

- **Absolute units (px, pt, cm, in)**
  Fixed size, independent of everything else. Use for borders, shadows, icons, and print styles. Avoid for font sizes and main layout widths, since px text ignores the user's browser font setting.
  Example:

```
    width: 350px;
    height: 800px;
    font-size: 12pt;
    margin: 2cm;
```

- **Font-based units (rem, em, ch)**
  Relative to font size. Use rem for font sizes and global spacing (respects user settings), em for spacing inside components like buttons (scales with the component's own font), and ch for readable line length (max-width: 65ch). Beware that em compounds when nested.
  Example:
  _font-size: 2rem;
  _padding: 0.5em 1em;
  _p {
  max-width: 65ch;
  }
- **Viewport units (vw, vh, vmin, dvh)**
  The viewport is the visible area of the browser window. Viewport units size things as a percentage of that area.
  - 1vw = 1% of the screen's width
  - 1vh = 1% of the screen's height
  - 100vh = the full screen height

  Use them for: full-screen banners, elements that should fit any screen, and big headings that grow with the screen.
